

Electromagnetic Theory II: Homework 7

Due: 19 February 2021

1 Boundary conditions: electric fields

Two conducting spherical shells are concentric. The inner shell has radius a and free surface charge Q that is uniformly distributed. The outer shell has radius b and free charge surface $-Q$, also distributed uniformly. The region between the shells is filled with a linear dielectric with dielectric constant ϵ_r .

- a) Determine the electric field everywhere.
- b) Verify that the *electric field* boundary conditions are satisfied at each spherical shell.

2 Boundary conditions: magnetic field

An infinitely long hollow cylinder has radius R . The cylinder carries a uniform surface current, in cylindrical coordinates,

$$\mathbf{K} = K \hat{\phi}$$

where $K > 0$ is constant.

- a) Determine the magnetic field at all locations.
- b) Verify that the *magnetic field* boundary conditions are satisfied at the cylinder boundary.
